Abstract. The paper deals with numerical modeling of binary alloys solidification process with motion of the fluid in the liquid and mushy zone. The mathematical model of the phenomenon is presented. Finite Element Method is used for modeling process. The results of the numerical simulation in the 2D region are discussed.

1. Mathematical model

Solidifying region is divided into three subregions (Fig. 1) with different physical properties. The liquid area $\Omega_L$ is filled with moving liquid alloy, the area $\Omega_S$ contains non-moving solid material and $\Omega_{L+S}$ is filled with mixture of liquid and solid phases.

Mathematical model consists of heat transport equation with convection term, momentum equation with buoyancy and Darcy’s drag term and continuity equation.
The value of the artificial heat capacity $c^*$ is calculated based on the following relation \[3\]

\[
c^*(T) = \begin{cases} 
  
  \frac{c_i \rho_i}{2} \left( T < T_i \right), & T < T_i \\
  \left( c_i \rho_i + c_j \rho_j \right) - \rho_j L \left( 1 - \phi(T) \right) \frac{\partial}{\partial T}, & T_i \leq T \leq T_f \\
  c_j \rho_j, & T > T_f 
\end{cases}
\] \[4\]

where $\phi(T)$ is porosity coefficient defined as

\[
\phi(T) = \begin{cases} 
  0, & T < T_s \\
  \frac{T - T_s}{T_i - T_s}, & T_s \leq T \leq T_i \\
  1, & T > T_i 
\end{cases}
\] \[5\]

Equations (1)-(3) are completed by the Dirichlet, Neumann and Newton boundary conditions

\[
X \in \Gamma_1 : T = T_b
\] \[6\]

\[
X \in \Gamma_2 : -\lambda n \cdot \text{grad}T = q_b
\] \[7\]

\[
X \in \Gamma_3 : -\lambda n \cdot \text{grad}T = \alpha(T - T_w)
\] \[8\]

and following initial conditions

\[
X \in \Gamma_{i-3} : u_i = 0
\] \[9\]

\[
t = 0 : T = T_0, \quad u_i = 0
\] \[10\]

Permeability of the porous region is calculated based on Karman-Kozeny relation \[2\]

\[
K = \frac{d \rho^2 \phi^3(T)}{180(1 - \phi(T))^2}
\] \[11\]
where \( d_p \) is average pore diameter depending on the size of the forming grains. Material properties are averaged using following formula

\[
\rho = \phi(T)\rho_i + [1 - \phi(T)]\rho_s \\
\lambda = \phi(T)\lambda_i + [1 - \phi(T)]\lambda_s
\]

(12)

2. Numerical model

The weighted residual method for the heat transport equation (1) is introduced

\[
\int_{\Omega} w \left[ \lambda \frac{\partial T}{\partial t} - c^* \left( T \left( \frac{\partial T}{\partial t} + u_i T_{,i} \right) \right) \right] d\Omega = 0
\]

(13)

Weak form of (13) is presented

\[
\lambda \int_{\Omega} w_i T_{,i} d\Omega + c^* \int_{\Omega} w_i u_i T_{,i} d\Omega + c^* \int_{\Gamma} w_i \frac{\partial T}{\partial t} d\Omega = \int_{\Gamma} w_i q \, d\Gamma
\]

(14)

Equation (14) is discretized over space using Petrov-Galerkin method. For the finite element one can write

\[
\lambda \int_{\Omega^{(i)}} w_i N_{j,k} d\Omega^{(c)} + c^* \int_{\Omega^{(i)}} w_i N_{j,k} N_{j,k} d\Omega^{(c)} = \int_{\Gamma^{(c)}} w_i q \, d\Gamma^{(c)}
\]

(15)

where \( N_i \) is linear shape function of the finite element and \( w_i \) can be written as follows

\[
w_i = N_i + \gamma_i \frac{h_i}{2} \left( \frac{u_i N_{i,k}}{u} \right)
\]

(16)

where

\[
\gamma_i = \text{ctg} h(Pe_i) - \frac{1}{Pe_i}
\]

(17)

\[
Pe_i = \frac{\rho c^* |u| h_i}{2 \lambda}
\]

(18)

Integral terms from (15) can be written in the following matrix form:

\[
K^{(c)} = \lambda \int_{\Omega^{(c)}} w_i N_{j,k} d\Omega^{(c)}
\]

(19)
\[
A^{(e)} = e^* \int_{\Omega^{(e)}} w_i N_j u_k^e N_{jk} d\Omega^{(e)} \tag{20}
\]
\[
M^{(e)} = e^* \int_{\Omega^{(e)}} w_i d\Omega^{(e)} \tag{21}
\]
\[
B^{(e)} = \sum_{f=1} w_i g_{ij} d\Gamma^{(e)} \tag{22}
\]

where \( K^{(e)} \) is element heat conductivity matrix, \( A^{(e)} \) - advection matrix, \( M^{(e)} \) - heat capacity matrix and \( B^{(e)} \) - right hand side vector.

After procedure of discretization over time (Euler backward scheme) and aggregation of the discrete model we obtain global finite element equation

\[
(K + A + \frac{J}{\Delta t} M) T^{f+1} = \frac{J}{\Delta t} MT^f + B \tag{23}
\]

We solve Navier-Stokes equation (2) by a characteristic based split (CBS) scheme based on the projection metod of Chorin [1] as described in Zienkiewicz and Codina [4] and Zienkiewicz and Taylor [5]. In this metod an auxiliary velocity field \( u^* \) is introduced to uncouple equations (2) and (3):

\[
\Delta u^*_i = u^*_i - u^f = \Delta t \left[ \frac{\mu}{\rho} u^*_{i,j} - u_{i,j}^f - \frac{\mu}{\rho K} u_i - \delta_{ij} g_{ij} \beta (T - T_{ref}) \right] +
\]

\[
+ \frac{\Delta t}{2} u_{i,j} \left[ u_{i,j}^f + \delta_{ij} g_{ij} \beta (T - T_{ref}) \right]_{ref} \tag{24}
\]

The final velocity field is corrected by the pressure increment so that is divergence free:

\[
u_i^{f+1} - u_i^* = \frac{\Delta t}{\rho} \left( p_{ii} \right)^{f+1} \tag{25}
\]

By taking the divergence of (25) we arrive at the following Poisson equation for the pressure:

\[
\Delta t (p_{ii})^{f+1} = \rho u_i^{*}_{,i} \tag{26}
\]

We apply the standard Galerkin procedure for (24)-(26).
3. Example of the numerical simulation

The computer simulation of the solidification process of the casting in the sand mould was made. The boundary and initial conditions are presented in the picture.

![Boundary and initial conditions](image)

In Figure 3 we can see velocity field after 50, 250 and 550 s. The movement of the liquid alloy can be observed in the liquid and porous region.

After 50 s we observe convection cells in the pure liquid region (Fig. 3a). The rest of the casting is filled with porous material. Velocities in this area are smaller than in the central region of the casting.

![Three stages of solidification process in the casting](image)

After 250 s pure liquid region is vanished and the entire area of the casting is filled with mixture of the liquid and solid (Fig. 3b). We can see the stream of the liquid material which flows from the bottom to the top of the casting. On the top it divides into two streams.
After 550 s there are pure solid areas in the corners of the casting. The rest of the solidifying region contains porous material. The motion of the fluid slowly vanishes due to solid fraction continuous growth.

Conclusions

Analysing the results of the numerical simulation it can be concluded that wide mushy region appears in the casting solidifying in the sand mould. The material properties of the sand mould guarantees low cooling rates, so the mushy zone can evolve so easily. Low cooling rates in the casting favours equiaxed solidification.
