Abstract. The one-dimensional time-fractional advection-diffusion equation with the Caputo time derivative is considered in a half-space. The fundamental solution to the Dirichlet problem and the solution of the problem with constant boundary condition are obtained using the integral transform technique. The numerical results are illustrated graphically.

Keywords: Caputo fractional derivative, advection-diffusion equation, Laplace integral transform, Fourier sine transform, Mittag-Leffler function

1. Introduction

Fractional calculus (the theory of integrals and derivatives of arbitrary order) has many applications in different areas of physics, biology and engineering [1-5]. The time-fractional advection-diffusion equation

\[
\frac{\partial^\alpha c(x,t)}{\partial t^\alpha} = a \Delta c - \mathbf{v} \cdot \nabla c
\]  

(1)

describes diffusion or heat conduction with additional velocity field, transport processes in porous media or groundwater hydrology. This equation can be obtained as a consequence of the balance equation for mass and the time-nonlocal constitutive equation for the matter flux with the “long-tail” power kernel [6] (compare the analysis of [6] with the analysis of the generalized Fourier or Fick law carried out in [7-10]). The comprehensive survey of literature on the fractional advection-diffusion equation can be found in [11]. In the previous paper [12] the fundamental solution to the Cauchy problem for time-fractional advection-diffusion equation with one spatial variable was obtained in the domain \(-\infty < x < \infty\). In the present paper we study the Dirichlet problem for this equation in a half-line \(0 < x < \infty\). Two types of boundary conditions are considered: the Dirac delta boundary condi-
tion for the fundamental solution and the constant boundary condition for the sought-for function.

2. The fundamental solution to the Dirichlet problem

We consider the time-fractional advection-diffusion equation

$$\frac{\partial^\alpha c(x,t)}{\partial t^\alpha} = a \frac{\partial^2 c(x,t)}{\partial x^2} - v \frac{\partial c(x,t)}{\partial x},$$  \hspace{1cm} (2)

where $0 < \alpha \leq 1$, $0 < x < \infty$, $0 < t < \infty$, $a > 0$, $v > 0$. In equation (2) $\partial^\alpha c / \partial t^\alpha$ is the Caputo fractional derivative of the order $\alpha$ [13]:

$$\frac{\partial^\alpha c}{\partial t^\alpha} = \frac{1}{\Gamma(n-\alpha)} \int_0^t (t-\tau)^{n-\alpha-1} \frac{\partial^{\alpha} c(\tau)}{\partial \tau^{\alpha}} d\tau, \hspace{1cm} n-1 < \alpha < n,$$

where $\Gamma(x)$ is the gamma function. Equation (3) simplifies for $0 < \alpha < 1$:

$$\frac{\partial^\alpha c}{\partial t^\alpha} = \frac{1}{\Gamma(1-\alpha)} \int_0^t \frac{1}{(t-\tau)^\alpha} \frac{\partial c(\tau)}{\partial \tau} d\tau. \hspace{1cm} (4)$$

The equation (2) is considered under zero initial condition

$$c(x,0) = 0,$$

and the Dirichlet boundary condition

$$c(0,t) = g_0 \delta(t)$$

with $\delta(t)$ being the Dirac delta function. In the above condition we have introduced the constant multiplier $g_0$ to obtain the nondimensional quantity displayed in figures.

The zero condition at infinity is imposed as follows:

$$\lim_{x \to \infty} c(x,t) = 0.$$  \hspace{1cm} (7)

Introducing the new sought-for function

$$c(x,t) = \exp \left( \frac{v \chi}{2a} \right) u(x,t),$$

where $u(x,t)$ is the fundamental solution for the constant boundary condition for the sought-for function.
the initial-boundary-value problem (2), (5)-(7) is reduced to the following one:

\[ \frac{\partial^{\alpha} u(x,t)}{\partial t^{\alpha}} = \frac{d}{dx} \frac{\partial^{2} u(x,t)}{\partial x^{2}} - \frac{v^{2}}{4\alpha} u(x,t), \quad (9) \]

\[ u(x,0) = 0, \quad (10) \]

\[ u(0,t) = g_0 \delta(t), \quad (11) \]

\[ \lim_{x \to \infty} u(x,t) = 0. \quad (12) \]

To solve the Dirichlet problem under consideration we use the Fourier sine transform with respect to the spatial coordinate \( x \):

\[ F\{u(x)\} = \tilde{u}(\xi) = \int_{0}^{\infty} u(x) \sin(\xi x) \, dx, \quad (13) \]

\[ F^{-1}\{\tilde{u}(\xi)\} = u(x) = \frac{2}{\pi} \int_{0}^{\infty} \tilde{u}(\xi) \sin(\xi x) \, d\xi. \quad (14) \]

The Fourier sine transform of the second order derivative of a function is defined by the relation:

\[ F\left\{ \frac{d^{2} u(x)}{dt^{2}} \right\} = -\xi^{2} \tilde{u}(\xi) + \xi u(0). \quad (15) \]

Application of the Fourier sine transform (13) to equation (9) using (15) leads to

\[ \frac{\partial^{\alpha} \tilde{u}(\xi,t)}{\partial t^{\alpha}} = \left( -\xi^{2} - \frac{v^{2}}{4\alpha} \right) \tilde{u}(\xi,t) + a \xi g_0 \delta(t). \quad (16) \]

Next, we use the Laplace transform with respect to the time \( t \). For the function \( u(t), \ 0 < t < \infty \), this transform is defined by

\[ L\{u(t)\} = U(s) = \int_{0}^{\infty} e^{-st} u(t) \, dt \quad (17) \]
with the inverse carrying out according to the Fourier-Mellin formula

\[ L^{-1}\{u^*(s)\} = u(t) = \frac{1}{2\pi i} \int_{\gamma-i\infty}^{\gamma+i\infty} e^{st} u^*(s) \, ds, \quad (18) \]

where \( \gamma \) is a positive fixed number.

For the Laplace transform rule the Caputo fractional derivative requires the knowledge of the initial values of the function and its integer derivatives of the order \( k = 1, 2, \ldots, n-1 \):

\[ L\left\{ \frac{d^\alpha u(t)}{dt^\alpha} \right\} = s^\alpha u^*(s) - \sum_{k=0}^{n-1} s^{\alpha-1-k} u^{(k)}(0^+) , \quad n-1 < \alpha \leq n. \quad (19) \]

Equation (19) simplifies for \( 0 < \alpha < 1 \):

\[ L\left\{ \frac{d^\alpha u(t)}{dt^\alpha} \right\} = s^\alpha u^*(s) - s^{\alpha-1} u(0^+). \quad (20) \]

Applying the Laplace transform to equation (17) and taking into account the rule (20) with the initial condition (10) gives

\[ s^\alpha \tilde{u}^*(\xi, s) = \left( -a\xi^2 - \frac{v^2}{4a} \right) \tilde{u}^*(\xi, s) + a g_0 \xi. \quad (21) \]

In the transform domain we get:

\[ \tilde{u}^*(\xi, s) = a g_0 \frac{\xi}{s^\alpha + a\xi^2 + \frac{v^2}{4a}}. \quad (22) \]

Inversion of the integral transforms results in the solution:

\[ u(x, t) = \frac{2a g_0}{\pi} t^{\alpha-1} \int_0^\infty E_{\alpha, \alpha} \left[ -\left( a\xi^2 + \frac{v^2}{4a} \right) t^\alpha \right] \xi \sin(\xi x) d\xi, \quad (23) \]

where the formula [8]

\[ L^{-1}\left\{ \frac{s^{\alpha-\beta}}{s^\alpha + b} \right\} = t^{\beta-1} E_{\alpha, \beta}(-bt^\alpha) \quad (24) \]
has been used with $E_{\alpha,\beta}(z)$ being the Mittag-Leffler function in two parameters $\alpha, \beta$ and having the series representation

$$E_{\alpha,\beta}(z) = \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(\alpha n + \beta)}, \quad \alpha, \beta > 0. \quad (25)$$

Returning to the quantity $c(x,t)$ according to (8), we get

$$c(x,t) = \frac{2a g_0}{\pi} \exp\left(\frac{v x}{2a}\right) r^{a-1} \int_0^\infty E_{\alpha,\alpha} \left[ -\left( a \xi^2 + \frac{v^2}{4a} \right) r^\alpha \right] \xi \sin(\xi x) d\xi. \quad (26)$$

The quantities appearing in the fractional advection-diffusion equation (2) and the boundary condition (5) have the following physical units: $[c] = \text{kg/m}^3$, $[x] = \text{m}$, $[t] = \text{s}$, $[a] = \text{m}^2/\text{s}^\alpha$, $[v] = \text{m/s}^\alpha$, $[g_0] = \text{kg} \cdot \text{s/m}^3$. At a level of individual particle motion the classical diffusion ($\alpha = 1$) corresponds to the Brownian motion which is characterized by a mean-squared displacement increasing linearly with time

$$\left\langle x^2 \right\rangle \approx at \quad \text{with} \quad [a] = \text{m}^2/\text{s}$$

Anomalous diffusion is exemplified by a mean-squared displacement with the power law time dependence

$$\left\langle x^2 \right\rangle \approx at^\alpha \quad \text{with} \quad [a] = \text{m}^2/\text{s}^\alpha$$

Using the nondimensional quantities

$$\bar{x} = \frac{x}{\sqrt{a} t^{\alpha/2}}, \quad \bar{\xi} = \sqrt{a} t^{\alpha/2} \xi, \quad \bar{v} = \frac{v}{\sqrt{a}}, \quad \bar{c} = \frac{tc}{g_0}, \quad (27)$$

one obtains the following solution:

$$\bar{c}(\bar{x}) = \frac{2}{\pi} \exp\left(\frac{\bar{v} \bar{x}}{2}\right) \int_0^\infty E_{\alpha,\alpha} \left[ -\bar{\xi}^2 - \frac{\bar{v}^2}{4} \right] \bar{\xi} \sin(\bar{\xi} \bar{x}) d\bar{\xi}. \quad (28)$$

The results of numerical calculations for different values of the drift parameter $\bar{v}$ and the order of the time-fractional derivative $\alpha$ are shown in Figures 1-4.
Fig. 1. The fundamental solution to the Dirichlet problem for $\alpha = 1$

Fig. 2. The fundamental solution to the Dirichlet problem for $\alpha = 0.5$

Fig. 3. The fundamental solution to the Dirichlet problem for $\alpha = 0$
Next we consider the time-fractional advection-diffusion equation (2) under zero initial condition (5), the condition (7) at infinity and the Dirichlet boundary condition with constant boundary value of the sought-for function:

\[ c(0,t) = c_0. \] (29)

As above, the new sought-for function \( u \) is introduced (see (8)), and the Laplace transform with respect to time and the Fourier sine transform with respect to the spatial coordinate give the solution in the transform domain:

\[ \hat{u}^\alpha(\xi,s) = ac_0 \frac{\xi}{s^{\alpha} + a\xi^2 + \frac{v^2}{4a}}. \] (30)

Taking into account that

\[ \frac{1}{s^{\alpha} + a\xi^2 + \frac{v^2}{4a}} = \frac{1}{a\xi^2 + \frac{v^2}{4a}} \left[ \frac{1}{s} - \frac{s^{\alpha-1}}{s^{\alpha} + a\xi^2 + \frac{v^2}{4a}} \right], \] (31)

we obtain
\[ u'(\xi, s) = c_0 \frac{\xi}{\xi^2 + \frac{v^2}{4a^2}} \left[ \frac{1}{s} - \frac{s^{\alpha-1}}{s^\alpha + a \xi^2 + \frac{v^2}{4a}} \right] \]  
\[ (32) \]

or, after inversion of the integral transforms,

\[ u(x,t) = \frac{2c_0}{\pi} \int_0^\infty \frac{\xi \sin(\xi x)}{\xi^2 + \frac{v^2}{4a^2}} \left[ 1 - E_\alpha \left[ -a \left( a \xi^2 + \frac{v^2}{4a} \right)^\alpha \right] \right] d\xi. \]

\[ (33) \]

In this case \( E_\alpha(z) \equiv E_{\alpha,1}(z) \) is the Mittag-Leffler function in one parameter \( \alpha \) (see the series representation (25) with \( \beta = 1 \)).

Taking into account the following integral [14]:

\[ \int_0^\infty \frac{\xi \sin(\xi x)}{\xi^2 + \frac{v^2}{4a^2}} d\xi = \frac{\pi}{2} \exp \left( \frac{-vx}{2a} \right) \]

\[ (34) \]

and returning to the quantity \( c(x,t) \) according to (8), we get

\[ c(x,t) = c_0 \left[ 1 - \frac{2}{\pi} \exp \left( \frac{vx}{2a} \right) \int_0^\infty \frac{\xi \sin(\xi x)}{\xi^2 + \frac{v^2}{4a^2}} \left[ 1 - E_\alpha \left[ -a \left( a \xi^2 + \frac{v^2}{4a} \right)^\alpha \right] \right] d\xi \right] \]

\[ (35) \]

and

\[ \overline{c}(\overline{x}) = 1 - \frac{2}{\pi} \exp \left( \frac{\overline{vx}}{2} \right) \int_0^\infty \frac{\overline{\xi} \sin(\overline{\xi} \overline{x})}{\overline{\xi}^2 + \frac{\overline{v}^2}{4}} E_\alpha \left[ -\overline{v}^2 - \frac{\overline{v}^2}{4} \right] d\overline{\xi}, \]

\[ (36) \]

where

\[ \overline{c} = \frac{c}{c_0}, \]

\[ (37) \]

other nondimensional quantities are the same as in (27).

The results of numerical calculations according to the solution (36) are shown in Figures 5-8 for different values of the drift parameter \( \overline{v} \) and the order of the time-fractional derivative \( \alpha \).
The Dirichlet problem for the time-fractional advection-diffusion equation in a half-space

Fig. 6. The solution to the Dirichlet problem with constant boundary value of a function for $\alpha = 0.5$

Fig. 7. The solution to the Dirichlet problem with constant boundary value of a function for $\nabla = 0$
4. Conclusions

We have considered the time-fractional advection-diffusion equation with the Caputo fractional derivative in the case of one spatial coordinate in the semi-infinite domain $0 < x < \infty$. The Laplace transform with respect to time and the Fourier sine transform with respect to the spatial coordinate have been used. The fundamental solution to the Dirichlet problem and the solution to the problem with constant boundary condition for the sought-for function have been obtained. The results of numerical calculations are displayed in figures for different values of the drift parameter $\varpi$ and the order $\alpha$ of the Caputo fractional derivative. It is seen from the figures that decreasing of the order of the fractional derivative $\alpha$ (taking memory into account) leads to retardation of the mass transport process (both the pure diffusion and the influence of the drift parameter). This is due to the complicated internal structure of the modeled medium (the presence of pores, inclusions, combs, etc.) which causes the memory effects. The influence is more noticeable for the fundamental solution than in the case of constant boundary condition. The numerical calculations were carried out using the package Mathematica.
